Abstract. The purpose of this study is to demonstrate the potential of Imperialist Competitive Algorithm (ICA) for solving Blasius differential equation. This algorithm is inspired by competition mechanism among Imperialists and colonies and has demonstrated excellent capabilities such as simplicity, accuracy, faster convergence and better global optimum achievement in contrast to other evolutionary algorithms. To validate the proposed approach, the results of ICA were finally compared with exact solution of variational iteration method (VIM). Based on the results, current method can be easily extended to solve a wide range of problems.

Keywords: Blasius equation, Imperialist Competitive Algorithm, Variational Iteration Method.

1. Introduction

Blasius equation is one of the fundamental and basic equations of fluid dynamics, which described the velocity profile of the fluid in the boundary layer theory on a half infinite interval [4, 6]. Many researchers have investigated analytical and numerical solution methods to handle this problem[7, 11]. Most of the work reported...

In present study, the basic idea of Imperialist Competitive Algorithm (ICA) is introduced and applied to solve Blasius differential equation which satisfies the boundary conditions. Finally, in order to demonstrate the presented method, a comparison is made between present method and exact solution of variational iteration method (VIM) achieved by Abdul-Majid Wazwaz [20].

2. Basic idea of Imperialist competitive algorithm (ICA)

In 2007, Atashpaz-Gargari and Lucas [3] introduced the basic idea of Imperialist Competitive Algorithm (ICA) to solve the real world engineering and optimization problems. The proposed algorithm mimics the socialpolitical process of imperialism and imperialistic competition. ICA contains a population of agents or countries. The pseudo-code of the algorithm is as follows.

2.1 Step 1: Initial empires creation

Comparable to other evolutionary algorithms, the proposed algorithm starts by an initial population. An array of the problem variables is formed which is called Chromosome in GA and country in this algorithm. In a $N_{avr}$-dimensional optimization problem a country is a $1 \times N_{avr}$ array which is defined as follows:

$$country = [p_1, p_2, p_3, \ldots, p_{N_{avr}}].$$

A specified number of the most powerful countries, $N_{imp}$, are chosen as the imperialists and the remaining countries, $N_{col}$, would be the colonies which are distributed among the imperialists depending on their powers which is calculated using fitness function. The initial empires are demonstrated in Figure 1 where more powerful empires have greater number of colonies.

2.2 Step 2: Assimilation policy

To increase their powers, imperialists try to develop their colonies through assimilation policy where countries are forced to move towards them. A schematic description of this process is demonstrated in Figure 2.

The colony is drawn by imperialist in the culture and language axes (analogous to any dimension of problem). After applying this policy, the colony will get closer to the imperialist in the mentioned axes (dimensions). In assimilation, each colony moves with a deviation of $\theta$ from the connecting line between the colony and
its imperialist by $x$ units to increase the search area, where $\theta$ and $x$ are random numbers with uniform distribution and $\beta$ is a number greater than one and $d$ is the distance between the colony and the imperialist state. $\beta > 1$ causes the colonies to get closer to the imperialist state from both sides.

$$x \sim U(0, \beta \times d)$$

$$\theta \sim U(-\gamma, \gamma)$$

2.3 **Step 3: Revolution**

In each decade (generation), certain numbers of countries go through a sudden change which is called revolution. This process is similar to mutation process in GA which helps the optimization process escape local optima traps.

2.4 **Step 4: Exchanging the position of imperialist and colony**

As the colonies are moving towards the imperialist and revolution happens in some countries, there is a possibility that some of these colonies reach a better position than their respective imperialists. In this case, the colony and its relevant imperialist change their positions. The algorithms will be continued using this new country as the imperialist.
2.5 Step 5: Imperialistic competition

The most important process in ICA is the imperialistic competition in which all empires try to take over the colonies of other empires. Gradually, weaker empires lose their colonies to the stronger ones. This process is modelled by choosing the weakest colony of the weakest empire and giving it to the appropriate empire which is chosen based on a competition among all empires. Figure 3. demonstrates a schematic of this process.

![Figure 3. Imperialistic competition: The more powerful an empire is, the more likely it will possess the weakest colony of the weakest empire.](image)

In this figure, empire 1 is considered as the weakest empire, where one of its colonies is under competition process. The empires 2 to \( n \) are competing for taking its possession. In order to begin the competition, firstly, the possession probability calculated considering the total power of the empire which is the sum of imperialist power and an arbitrary percentage of the mean power of its colonies. Having the possession probability of each empire a mechanism similar to Roulette Wheel is used to give the selected colony to one of the empires considering a proportional probability.

2.6 Step 6: Convergence

Basically the competition can be continued until there would be only one imperialist in the search space. However, different conditions may be selected as termination criteria including reaching a maximum number of iterations or having negligible improvement in objective function. Figure 4. depicts a schematic view of this algorithm. Whenever the convergence criterion is not satisfied, the algorithm continues.

The main steps of ICA is summarized in a pseudo-code are given in Figure 5. The continuation of the mentioned steps will hopefully cause the countries to converge to the global minimum of the cost function. Different criteria can be used to stop the algorithm.

2.7 Literature Review

Imperialist Competitive Algorithm has been successfully applied to solve some engineering problems in recent years, some of those are mentioned below. In Atashpaz-Gargari et al. [2], ICA is used to design an optimal controller which not only decentralizes but also optimally controls an industrial Multi Input Multi Output (MIMO) distillation column process. Biabangard-Oskouyi et al. [5] used ICA for reverse analysis of an artificial neural network in order to characterize the properties of materials from sharp indentation test. Nazari et al. [18] solved the integrated
product mix-outsourcing (which is a major problem in manufacturing enterprise) using ICA. Kaveh and Talatahari [8] utilized the ICA to optimize design of skeletal structures. Yousefi et al. [21] presented the application of Imperialist Competitive Algorithm for optimization of cross-flow plate fin heat exchanger and concluded that ICA comparing to the traditional GA shows considerable improvements in finding the optimum designs in less computational time under the same population size and iterations. Mozafari et al. [17] applied ICA to optimize intermediate epoxy adhesive layer which is bonded between two dissimilar strips of material. Towsyfyan and Adnani compared the effectiveness of ICA and GA in optimization of welding process [19].

3. Problem Statement

It is well known that the Blasius equation is the mother of all boundary layer equations in fluid mechanics. The differential equation governing the free oscillation of the mathematical Blasius equation, when friction is neglected, is written as
follow:

\[
\ddot{u}(x) + \frac{1}{2} u(x) \dot{u}(x) = 0 \quad D : x \in [0, \infty],
\]

\[
u(0) = 0, \quad \dot{u}(0) = 0, \quad \ddot{u}(\infty) = 1. \tag{4}
\]

In order to solve Equation (4), assume a discretization of the domain D with m arbitrary points. Now, the problem can be transformed to the following set of equations:

\[
\ddot{u}(x_i) + \frac{1}{2} u(x_i) \dot{u}(x_i) = 0 \quad \forall x_i \in D, \quad i = 1, 2, 3, \ldots, n. \tag{5}
\]

Subject to given boundary conditions. With reference to work of E. Assareh et al. [1], the following nonlinear trial function is assumed as approximate solution:

\[
u_T = x - a_1 + a_2 e^{-x} + a_3 xe^{-x} + a_4 e^{-2x}, \tag{6}
\]

where \(\nu_T\) is trial function and \(\vec{a}\) (i.e. \(a_1\) to \(a_4\)) are adjustable parameters. These parameters should be determined regarding minimizing the following sum of squared errors, subject to given boundary conditions.

\[
Error(\vec{a}) = \sum_{i=1}^{m} \left( \ddot{\nu}_T(x_i) + \frac{1}{2} \nu_T(x_i) \dot{\nu}_T(x_i) \right)^2. \tag{7}
\]

According to the given boundary conditions in Equation (4), following equations are obtained between \(a_1\) to \(a_4\).

\[
a_3 = 2a_1 - a_2 - 1, \tag{8}
\]

\[
a_4 = a_1 - a_2. \tag{9}
\]

In order to calculate Error (\(\vec{a}\)) function, derivations respect to independent variable \(x\) are needed. Using Equations (8, 9) required terms in Equation (7) are written as follows:

\[
u_T(x_i) = x_i - a_1 + a_2 e^{-x_i} + (2a_1 - a_2 - 1)x_i e^{-x_i} + (a_1 - a_2)e^{-2x_i}, \tag{10}
\]

\[
u_T(x_i) = a_2 e^{-x_i} - (4a_1 - 2a_2 - 2)e^{-x_i} + 4(a_1 - a_2)e^{-2x_i} + (2a_1 - a_2 - 1)x_i e^{-x_i}, \tag{11}
\]

\[
u_T(x_i) = (6a_1 - 3a_2 - 3)e^{-x_i} - a_2 e^{-x_i} - 8(a_1 - a_2)e^{-2x_i} - (2a_1 - a_2 - 1)x_i e^{-x_i}. \tag{12}
\]

Now, the Imperialist Competitive algorithm can be applied in order to determine optimal values of \(a_1\) and \(a_2\) regarding minimizing Error (\(\vec{a}\)) function at the end, \(a_3\) and \(a_4\) will be calculated from Equations (8, 9).
4. Results and discussion

In this study, the collocation point locations at $x_i$ were used in interval $[2, 2.8]$ with step size of 0.2. After very careful investigation, ICA parameters were selected based on Table 1.

<table>
<thead>
<tr>
<th>ICA Parameters</th>

To choose the proper number of countries for the optimization, the algorithm is executed for different number of initial countries and the respected results for the minimum objective (Error) function at different $x_i$ locations can be seen in Figure 6. Due to the stochastic nature of the algorithm, each execution of the algorithm results in a different result. Therefore, in the entire study the best solution out of 10 executions is presented as the optimization result. According to Figure 6, it can be seen that in this study the variation of the target (Error) function is very high for the number of countries less than 100. Although more increase in the number of initial countries yields in decrease in the objective function, the changes are not considerable. Therefore, the number of countries for this study is set to 100 for the rest of the paper.

Figure 6. Effect of variation of the number of countries on the Error function.
Figure 7 demonstrates the iteration process of ICA method for optimization of objective (Error) function at different $x_i$ locations in interval $[2, 2.8]$. A significant decrease in the target (Error) function is seen in the beginning of the evolution process. After certain decades the changes in the fitness function become relatively minute.

In this optimization process, initial number of countries is 100 which 5 of the best ones are chosen to be the imperialists and control others. Since the optimization problem is finding the optimal values of $a_1$ and $a_2$ regarding the minimum Error($\vec{a}$) function, the results for the best solution of corresponding adjustable parameters are demonstrated in Table 2. At the end, $a_3$ and $a_4$ will be calculated from Equations (8, 9).

Table 2. the results for the best solution of corresponding adjustable parameters.

A careful investigation is carried out to compare the design efficiency of the proposed algorithm with variational iteration method (VIM) achieved by Abdul-Majid Wazwaz [20]. The results are demonstrated in Table 3, it can be concluded that the results of ICA are in good agreement with the work of Abdul-Majid Wazwaz [20].

5. Conclusions

In this study, Imperialist Competitive Algorithm (ICA) was applied in order to find the adjustable parameters of approximation function regarding the minimum fitness function. These parameters were determined so that the approximation function has to satisfy the boundary conditions. In order to demonstrate the presented method, a comparison was made between the current method here and in the literature. The results showed that our proposed method is in good agreement with obtained solution in the literature. In general, ICA has a promising potential to be used as a new solution approach in a variety of problems.

6. Acknowledgments

The authors would like to thank, Dr. M. Ghalambaz, for his valuable comments and the first author would like to appreciate reviewers and journals editor in chief.
