\begin{abstract}
A mathematical model for nutritional transport in capillary tissues exchange system in the presence of magnetic field has been studied. In this case, the cell is deformed. Due to concentration gradients, the dissolved nutrient in substrate diffuses into surrounding tissue. The analytical method is based on perturbation technique while the numerical simulation is based on finite difference scheme. Results concerning the concentration of dissolved nutrients, diffusive flux, normal component of velocity and skin friction coefficient, indicate that the presence of magnetic field influences the flow field considerably.

1. Introduction

The most physiologically important function of blood circulation through capillaries is to supply nutrients to every living cell of the organism and also to remove various waste products from every cell. Nutrient, dissolved in plasma, enter the tissue from capillary wall. The material is transported by convection and diffusion in the capillary, whereas in the tissue the material is transported through diffusion only as the convection velocity in the tissue is small. Blood can be regarded as a magnetic fluid because the red blood cell (RBC) contain the hemoglobin molecule.
a form of iron oxide. So when we apply a magnetic field on the blood the only components of blood response to these field are erythrocytes. Pauling and Coryell are the first who reported that the erythrocytes orient with their disk plane parallel to the magnetic field [13]. Knut Aukland was found that other cell of blood, except the erythrocytes, like platelets, also orient with the applied magnetic field [11].

In order to investigate the flow of a biomagnetic fluid under the action of an applied magnetic field Haik [10] and Tzirtzilakis [21, 22] developed the mathematical model of Biomagnetic fluid dynamics. Rudraiah [15] have investigated the effect of slip and electrically conducting viscous fluid in a horizontal channel bounded on both sides by porous substrates of finite thickness. Two, three region flow models have also been developed Gupta [8]. Secomb [16–18], Tandon [19, 20] and Bali [1] developed Mathematical models for flow in narrow capillaries with diameter less than 8\(\mu m\) in which red cell travel as single file almost filling the lumen. Bali [2] also studied the nutritional transport through the plasma, in between the cell and capillary wall, into the tissue. Bharadwaj [5] analyzed the squeezing flow of red blood cell through a very narrow capillary enclosed by a tissue. Deepti Seth [7] concerned with the formulation of a simple mathematical model for the transport of oxygen from the surrounding retinal tissue.

In this paper, our aim is to study the deformation of cell on nutrition transport in capillary-tissue exchange in the presence of magnetic field. The momentum equation is solved analytically for velocity distribution. A first order perturbation method satisfying the slip-velocity at the porous surface is used. Knowing the average velocity field, we solve the diffusion equation numerically by employing a finite difference scheme.

2. Mathematical Formulation

The viscous, steady, two dimensional, incompressible, axis symmetrical, laminar biomagnetic fluid (blood) flow is considered taking place between two parallel flat plates (channel). We assume that the length of the channel version of a idealized krogh capillary-tissue exchange system is large compared to the width so that the end effects are negligible. A uniform magnetic field, \(H_0\) is applied in the y-direction and the magnetic Reynolds number is assumed to be sufficiently small so that the perturbations to the magnetic field may be neglected.

![Figure 1. Physical configuration.](image-url)
Flow region is divided into two sub-regions:
(i) Fluid film region
(ii) Porous tissue region.
Blood is considered as a homogeneous, electrically conducting biomagnetic fluid and Newtonian behavior is assumed. The force action on the erythrocytes when entering the magnetic field are shown in figure 1.

2.1 Governing Equations

2.1.1 Fluid Film Region

The governing equation of motion for the flow of plasma in between the cell and capillary tissue wall are given [6]

\[ u' \frac{\partial u'}{\partial x'} + v' \frac{\partial u'}{\partial y'} = -\frac{1}{\rho} \frac{\partial p'}{\partial x'} + \nu \left( \frac{\partial^2 u'}{\partial x'^2} + \frac{\partial^2 u'}{\partial y'^2} \right) - \frac{\mu^2 \sigma_0 H_0^2}{\rho} u' \quad (1) \]

\[ u' \frac{\partial v'}{\partial x'} + v' \frac{\partial v'}{\partial y'} = -\frac{1}{\rho} \frac{\partial p'}{\partial y'} + \nu \left( \frac{\partial^2 v'}{\partial x'^2} + \frac{\partial^2 v'}{\partial y'^2} \right) \quad (2) \]

but due to small leakage in to the porous wall we retain the continuity equation as:

\[ \frac{\partial u'}{\partial x'} + \frac{\partial v'}{\partial y'} = 0 \quad (3) \]

The Boundary conditions are

\[ u' = -\frac{\sqrt{k}}{\alpha} \frac{\partial u'}{\partial y'} \quad \text{at} \quad y' = \pm h \quad (4) \]

\[ \frac{\partial u'}{\partial y'} = 0 \quad \text{at} \quad y' = 0 \quad (5) \]

\[ v' = 0 \quad \text{at} \quad y' = 0 \quad (6) \]

\[ v' = v_w \quad \text{at} \quad y' = \pm h \quad (7) \]

where, \( u \) and \( v \) are the \( x \) and \( y \) components of the velocity, \( p \) is the pressure, \( \sigma_0 \) is the electrical conductivity, \( \rho \) is the density of the fluid, \( v_w \) is the vertical velocity in the porous layer, \( k \) is the permeability of the medium, \( \alpha \) is the slip parameter, \( \mu \) is the kinematic viscosity and \( 2h \) is the width of the channel Eq. (4) is the Beavers and Joseph (BJ) slip condition [3] at the lower and upper permeable surface.

To solve the Eqs (1)-(3), we use the following non dimensional quantities

\[ y = \frac{y'}{h}, \phi = \frac{1}{\alpha \sigma}, \sigma = \frac{h}{\sqrt{k}} \]
For incompressible flows, the velocity vector \( V \) can be expressed in terms of a vector potential \( \psi \) as

\[
V = \nabla \times \psi
\]

This solution technique was first formulated by Berman [4]. By introducing the dimensionless stream function \( \psi = \psi(x, y) \) defined by the expressions

\[
u = \frac{\partial \psi}{\partial y'} = - \frac{1}{h} \frac{\partial \psi}{\partial y}
\]

\[
v = \frac{\partial \psi}{\partial x'}
\]

Now, we choose an appropriate form for the stream function as

\[
\psi = [hu_0 - v_w x']f(y)
\]

Substituting Eq.(10) into Eqs.(8) and (9), the velocity components are

\[
u = [u_0 - v_w x']f'(y)
\]

\[
v = v_w f(y)
\]

By eliminating the pressure \( p \) from the first two and substituting (11) and (12) in (1) and (2), we obtained

\[
\frac{\partial}{\partial y} [Re_w(f'^2 - f f'') + f'''(y) - M^2 f'] = 0
\]

Integrating (13) once, we get

\[
[Re_w(f'^2 - f f'') + f'''(y) - M^2 f'] = K
\]

where, \( K \) is the constant of integration, \( Re_w = \frac{v_w h}{\nu} \) is the Reynolds number, \( M = \mu H_0 h \sqrt{\frac{2\alpha}{\rho}} \) is the Hartmann number.

The boundary conditions (4)-(7) in non-dimensional form are:

\[
f'(y) = -\phi f''(y) \quad \text{at} \quad y = 1
\]

\[
f''(y) = 0 \quad \text{at} \quad y = 0
\]

\[
f(y) = 0 \quad \text{at} \quad y = 0
\]
$$f(y) = 1 \text{ at } y = 1 \quad (18)$$

### 2.2 Nutritional Transport

#### 2.2.1 Porous Tissue Region

Under the admissible assumptions, the approximate diffusion equation in porous matrix is given [14]

$$\pi n \frac{\partial C'}{\partial x'} + \pi \frac{\partial C'}{\partial y'} = D' \left( \frac{\partial^2 C'}{\partial x'^2} + \frac{\partial^2 C'}{\partial y'^2} \right) + m' \quad (19)$$

where, $C'$ the concentration of dissolved nutrients in the tissue region, $D'$ is the diffusion coefficient, $\pi n$ and $\pi$ is the average velocity and $m'$ is the rate of production of the nutrient within the tissue.

we assume that the longitudinal diffusion is much less than the transverse, that is $\frac{\partial^2 C'}{\partial x'^2} \ll \frac{\partial^2 C'}{\partial y'^2}$. Thus (19) can be rewritten as

$$\pi n \frac{\partial C'}{\partial x'} + \pi \frac{\partial C'}{\partial y'} = D' \frac{\partial^2 C'}{\partial y'^2} + m' \quad (20)$$

The boundary conditions are:

$$C' = c_0 \text{ at } x' = 0 \quad (21)$$

$$C' = \eta c_0 \text{ at } y' = h \quad (22)$$

$$\frac{\partial C'}{\partial y'} = 0 \text{ at } y' = h + H' \quad (23)$$

Now we introduce the following non-dimensional quantities:

$$U = \frac{u'}{u_0}, V = \frac{v'}{v_w}, C = \frac{C'}{c_0}, \pi n = \frac{\pi n}{u_0}, \pi = \frac{\pi}{v_0}, H = \frac{H'}{h},$$

$$y = \frac{y'}{h}, x = \frac{u_w x'}{u_0 h} = \frac{4 Re_w x}{Re h}, Pe = \frac{v_w h}{D}, N = \frac{m'h}{c_0 v_0}, \alpha = \frac{1}{Pe}$$

where, $H$ is the thickness of Porous matrix, $v_0$ is the fluid velocity, $c_0$ is the uniform concentration of the nutrient in the capillary, $\eta$ is the partition coefficient [11]. Using the non-dimensional scheme, the Eq.(20) is transformed as given below,

$$\pi n \frac{\partial C}{\partial x} + \pi \frac{\partial C}{\partial y} = \alpha_0 \frac{\partial^2 C}{\partial y^2} + N \quad (24)$$

and the Boundary conditions are
\[ C = 1 \quad \text{at} \quad x = 0 \quad (25) \]
\[ C = \eta \quad \text{at} \quad y = 1 \quad (26) \]
\[ \frac{\partial C}{\partial y} = 0 \quad \text{at} \quad y = 1 + H \quad (27) \]

3. Method of Solution

3.1 Velocity distribution in capillary region

Solving the Eq.(14) using perturbation technique, we let

\[
f(y) = f_0(y) + \text{Re}_w f_1(y) + O(\text{Re}_w^2), \quad (28)
\]

and

\[
K = K_0 + \text{Re}_w K_1 + O(\text{Re}_w^2) \quad (29)
\]

where, \( f_n \)'s and \( K_n \)'s are independent of \( \text{Re}_w \) and \( \text{Re}_w \) is the perturbation parameter.

Substituting Eqs.(28) and (29) in Eq.(14) and collecting of like powers of \( \text{Re}_w \), we have the following sets of equations.

Zeroth order equations

\[
f'''_0 - M^2 f'_0 = K_0 \quad (30)
\]

The corresponding boundary conditions:

\[
f_0(y) = f'''_0(y) = 0 \quad \text{at} \quad y = 0 \quad (31)
\]

\[
f'_0(y) + \phi f'''_0(y) = 0, f_0(y) = 0 \quad \text{at} \quad y = 1 \quad (32)
\]

The Solution is

\[
f_0 = A_1 + A_2 e^{-M y} + A_3 e^{M y} - \frac{y K_0}{M^2} \quad (33)
\]

Using the boundary conditions (31) and (32), we obtained

\[
f_0 = \beta_1 \sinh M y + \beta_2 y \quad (34)
\]

and

\[
K_0 = -M^2 \beta_2 \quad (35)
\]
First order equations:

\[ f_1''' - M^2 f_1' = K_1 - f_0'^2 + f_0'' \]  

(36)

The corresponding boundary conditions are:

\[ f_1(y) = f_1''(y) = 0 \quad \text{at} \quad y = 0 \]  

(37)

\[ f_1'(y) + \phi f_1''(y) = 0, \; f_1'(y) = 0 \quad \text{at} \quad y = 1 \]  

(38)

The Solution is

\[ f_1 = B_1 + B_2 e^{-My} + B_3 e^{My} - \frac{y(K_1 - b_2^2 - b_1^2 M^2)}{M^2} \]  

(39)

Using the boundary conditions (37) and (38), we obtained

\[ f_1 = \alpha_1 y + \alpha_2 \sinh My + \alpha_3 y \cosh My + \alpha_4 y^2 \sinh My \]  

(40)

and

\[ K_1 = \alpha_5 \]  

(41)

Substituting Eqs.(34) and (40) in Eq.(28), Eqs.(35) and (41) in Eq.(29), are obtained a first-order perturbation solution as

\[ f(y) = (\beta_1 \sinh My + \beta_2 y) + Re_w \left( \alpha_1 y + \alpha_2 \sinh My + \alpha_3 y \cosh My + \alpha_4 y^2 \sinh My \right) \]  

(42)

and

\[ K = -M^2 \beta_2 + \alpha_5 Re_w \]  

(43)

where, \( \alpha_n^\ast \) and \( \beta_n^\ast \) are functions of \( \phi \) and \( A_1, A_2, A_3, B_1, B_2, B_3 \) are the constants, given in the Appendix A.

Using the non-dimensional quantities and substituting (42) in (11) and (12), we obtain the velocity profile as

\[ U = \left( 1 - \frac{4Re_w x}{Re h} \right) \left[ (\beta_2 + M \beta_1 \cosh My) + Re_w \{ \alpha_1 + (\alpha_2 M + \alpha_3) \cosh My \\
+ (\alpha_3 M + 2\alpha_4) y \sinh My + \alpha_4 My^2 \cosh My \} \right] \]  

(44)

and

\[ V = (\beta_2 y + \beta_1 \sinh My) + Re_w \left( \alpha_1 y + \alpha_2 \sinh My + \alpha_3 y \cosh My + \alpha_4 y^2 \sinh My \right) \]  

(45)
The normalized axial component of velocity obtained from (44) is

\[
\frac{U}{U} = (\beta_2 + M\beta_1 \cosh My) + Re_w \{\alpha_1 + (\alpha_2 M + \alpha_3) \cosh My \\
+ (\alpha_3 M + 2\alpha_4) y \sinh My + \alpha_4 M y^2 \cosh My\}
\]  

(46)

where,

\[
\overline{U} = \frac{1}{2} \int_{-1}^{1} u(y)dy = 1 - x
\]  

(47)

3.2 skin friction

In non-dimensional form, the coefficient of skin friction \(C_f\) is defined as

\[
C_f = \frac{\frac{\tau_w}{\frac{1}{2} \rho U^2}}{\frac{1}{2} \rho \frac{\partial U}{\partial y}} = 2 \frac{\partial U}{Re \partial y} \\
= \frac{2}{Re} \left(1 - \frac{4Re_w x'}{h} \right) [M^2 \beta_1 \sinh My + Re_w ((\alpha_2 M + \alpha_3) M \sinh My \\
+ (\alpha_3 M + 2\alpha_4)(yM \cosh My + \sinh My) + \alpha_4 M (y^2 M \sinh My + 2y \cosh My))]
\]

The coefficient of skin friction \(C_f\) at \(y = 1\) is defined as

\[
C_f = \frac{2}{Re} \left(1 - \frac{4Re_w x'}{h} \right) [M^2 \beta_1 \sinh M + Re_w ((\alpha_2 M + \alpha_3) M \sinh M \\
+ (\alpha_3 M + 2\alpha_4)(M \cosh M + \sinh M) + \alpha_4 M (M \sinh M + 2 \cosh M))]
\]  

(48)

3.3 Concentration distribution in tissue region

Solving Equation (24) using finite difference implicit scheme in \(y\) with the average velocity field obtained from (44) and (45). First choose the grid, \(i = 1\) at \(y = 1\), \(i = 2\)
at $y = 1 + \Delta y$, $i = 2$ at $y = 1 + 2\Delta y$ and so on to $i = NI$ at $y = 1.25$. Similarly, $j = 1$ at $x = 0$, where $\Delta y$ and $\Delta x$ are increments in the y and x-direction, respectively.

To find the unknown function of Equation (24) we use central difference for discretizing the second order and first order derivative and backward difference for the first order derivatives. Thus, with respect to $(i,j)$ point the discretization is

$$\frac{\partial^2 C}{\partial y^2} = \frac{C_{i+1,j} - 2C_{i,j} + C_{i-1,j}}{\Delta y^2},$$

(49)

$$\frac{\partial C}{\partial y} = \frac{C_{i+1,j} - C_{i-1,j}}{2\Delta y},$$

(50)

$$\frac{\partial C}{\partial x} = \frac{C_{i,j} - C_{i,j-1}}{\Delta x},$$

(51)

Substituting Equations (49)-(51) in Equation (20) we get

$$A_i C_{i-1,j} + B_i C_{i,j} + E_i C_{i+1,j} = F_i,$$

(52)

where,

$$A_i = -\frac{V}{2\Delta y} - \frac{\alpha_0}{\Delta y^2},$$

(53)

![Figure 3. Axial velocity profiles for different values of $\phi$.](image-url)
Using the Taylor series expansion for $i = 1$ and $i = NI$, the boundary conditions (26) and (27) become

$$C_{i,1} = \eta, \quad i = 1, 2, \ldots, NI.$$  \hspace{1cm} (57)

Solving the above Equations (52)-(56), can be written in a way that constitutes a scalar tridiagonal system along each $x$ grid line ($j$ constant) and which are solved using the Thomas Algorithm [12]. It can be seen that this scheme is implicit, considering each $j$ line constant, and therefore is called line by line implicit method (L.L.I.M.). The solution of the equation is achieved iteratively by solving, for all $j$ lines, the arising tridiagonal systems until the unknown function at all the grid points of the computational domain has been evaluated up to an accuracy. It was found that convergence of the numerical of the solution is satisfactory for grid size $0.025$ for $y$ and $0.1$ for $x$, solving methods are given in the Appendix B.

3.4 Diffusive flux

In non-dimensional form, Diffusive flux on the wall is given

$$D_J = -D \frac{\partial C}{\partial y} = -D \left\{ \frac{C_{i+1,j} - C_{i,j}}{\Delta y} \right\}$$  \hspace{1cm} (59)

4. Results and Discussions

Velocity profiles, skin friction coefficient, concentration distribution and diffusive flux of the flow field have been computed using MATHEMATICA 8.0. Figure 2 represent the variation of the velocity $U$ with axial distance $y$ for the fixed wall Reynolds number $Re_w = 0.1$. The curves are plotted for different values of the $M$ with $\phi = 0$. Clearly when Hartmann number increases, the axial velocity decreases and profiles get flatter and approach those of plug flow.

Figure 3 shows that as slip coefficient $\phi$ increases, the wall shear decreases and velocity profiles flatten for $M = 1$. Figures 4 and 5 shows the normalized axial components of velocity profiles which are plotted against $y$ for different values of Hartmann number and slip coefficient respectively. It is similar to figure 2 and 3.
which is independent of entrance Reynolds number and longitudinal position. Figure 6 depicts the coefficient skin friction $C_f$ at $y = 1$ increases as Hartmann number increase.

Figures 7 and 8 shows the concentration distribution in tissue region with longitudinal position $x$ and transverse position $y$ for different values of Hartmann number. In this region as Hartmann number increases, the concentration also increases. In this case, the cells of the tissue of the deeper region gets proper nutrition. Due to increase in Hartmann number, more fluids are enters into tissue so that more dissolved nutrients enter into the tissue along with fluid. Figure 9 represent the diffusive flux on the wall in tissue region at $y = 1$ with $x$. Diffusive flux on the wall increases for $M$ value increases. Therefore in deeper region also get proper nutrition.

5. Conclusion

The biomagnetic (blood) fluid flow in a channel with axi-symmetric is studied. The present analysis deals with the deformation of the cell are useful for continuous blood flow through a capillary in the presence of magnetic field. When the blood flow is increased nutrients are distributed to the tissues much more effectively and quickly, so that the tissue gets more nutrients.

6. Appendices

6.1 Appendix 1

Constant defined in Eqs.(33), (39) and (42) are

\[ A_1 = 0, \quad B_1 = 0 \]  
\[ A_1 = \frac{K_0}{M^2(2M \cosh M + 2\phi^2 \sinh M)} \]  
\[ A_4 = -\frac{K_0}{M^2(2M \cosh M + 2\phi^2 \sinh M)} \]  
\[ B_2 = \frac{1}{2M \cosh M + 2\phi^2 \sinh M} \left[ \frac{b_1^2 b_2 b_3}{4M} + \frac{7b_1 b_2 M \cosh M}{4M} + \frac{5b_1 b_2 \sinh M}{4} \right] 
- \frac{b_1 b_2 M \cosh M}{4} + 3b_1 b_2 \phi \sinh M + \frac{3b_1 b_2 M \phi \cosh M}{4} - \frac{b_1 b_2 M^2 \phi \sinh M}{4} \]  
\[ B_3 = -\frac{1}{2M \cosh M + 2\phi^2 \sinh M} \left[ \frac{b_1^2 b_2 b_3}{4M} + \frac{7b_1 b_2 M \cosh M}{4M} + \frac{5b_1 b_2 \sinh M}{4} \right] 
- \frac{b_1 b_2 M \cosh M}{4} + 3b_1 b_2 \phi \sinh M + \frac{3b_1 b_2 M \phi \cosh M}{4} - \frac{b_1 b_2 M^2 \phi \sinh M}{4} \]  
\[ \alpha_1 = -\frac{\beta_1^2 \beta_2 \beta_3}{4M}, \]  
\[ \alpha_2 = \frac{\beta_1 \beta_2 \beta_3}{4}, \]  
\[ \alpha_3 = -\frac{7\beta_1 \beta_2}{4M}, \]  
\[ \alpha_4 = \frac{\beta_1 \beta_2}{4}, \]  
\[ \alpha_5 = \frac{\beta_2^2 + M^2 \beta_1^2 + \beta_1^2 \beta_2 \beta_3 M}{4}, \]
\[ \beta_1 = -\frac{1}{M \cosh M - \sinh M + \phi M^2 \sinh M} \]  

(70)

\[ \beta_2 = -\beta_1 (M \cosh M + \phi M^2 \sinh M) \]  

(71)

\[ \beta_3 = 7M \cosh^2 M - 5M \sinh^2 M + 2\phi M^2 \sinh 2M - 7 \sinh M \cosh M - 12\phi M \sinh^2 M \]  

(72)

\[ \beta_4 = (\phi M^2 - 12\phi - 6) \sinh M + (M - 3\phi M) \cosh M \]  

(73)

6.2 Appendix 2

Solving the Eqs. (52)-(58) using Thomas algorithm for tridiagonal matrix

\[ b_i = \frac{B_i - A_i E_{i-1}}{b_{i-1}} \quad \text{with} \quad b_1 = B_1 \]  

(74)

\[ t_i = \frac{F_i - A_i t_{i-1}}{b_i} \quad \text{with} \quad t_1 = \frac{F_1}{B_1} \]  

(75)

Compute the backward from \( C_{N1,j} \) to \( C_{1,j} \) as follows:

\[ C_{i,j} = t_i - \frac{E_i C_{i+1}}{b_i} \quad \text{and} \quad C_{N1,j} = t_{NI} \]  

(76)
